Does cavitation cause pressure fluctuations in low-head pumped storage stations?

To comprehensively and realistically investigate the pressure fluctuations induced by cavitation in the pump device of low-head pumped storage stations, an experimental study is conducted on an actual pumped storage station located in Jiangsu Province, China.

Why are pumped storage stations important?

Renewable energy sources, such as solar and wind energy, are highly dependent on natural environments and climate changes for their power generation processes, thus exhibiting significant intermittent and unstable characteristics [1,2]. Pumped storage stations, as an efficient energy storage technology, play a crucial role in power systems.

What are the parameters of pumped storage system?

The parameters of the pumped storage system selected for this study are as follows: the designed flow rate is 50 m³/s (5 units), the designed net head is 9.5 m, and the speed is 1312.5 r/min.

Does cavitation affect hydraulic characteristics of pumped storage systems?

Researches indicate that cavitation has significant effects on the hydraulic characteristics of pumped storage systems, especially the cavitation characteristics under pump mode, which seriously restricts the development of pump devices [20,21].

Why do pumped storage power stations vibrate?

These intense pressure fluctuations further cause the intense vibration of the local components (such as columns, different floors, etc.) at the pumped storage power station [36,37]. In turbine mode, BPF and its harmonics are very noticeable for the entire load range due to RSI.

What causes hydraulic instability in high-head reversible pump-turbines?

In the high-head reversible pump-turbines, the most unfavourable hydraulic instability is the unstable pressure fluctuations in the vaneless space caused by interactions between the guide vanes and runner blades, known as rotor-stator interactions (RSI).
